

TTIC 31230 Fundamentals of Deep Learning

Problems For Fundamental Equations.

problem 1. This problem is on a CTC-like algorithm for image labeling.

Suppose that the training data consists of pairs $(I[X, Y], S)$ where I is an image and S is a set of object types occurring in the image. For example S might be $\{\text{Person, Dog, Car}\}$. To be concrete we can take \mathcal{C} to be the set of image labels used in CIFAR 100 and take S to be a subset of \mathcal{C} containing no more than five labels ($|S| \leq 5$). We want to do SGD on a model defining $P_{\Phi}(S \mid I[X, Y])$.

We will use a latent variable $z[X, Y]$ such that for pixel coordinates (x, y) we have $z[x, y] \in \mathcal{C} \cup \{\perp\}$. For a given $z[X, Y]$ define $S(z[X, Y])$ to be the set of classes appearing in $z[X, Y]$, i.e., $S(z[X, Y]) = \{c \mid \exists x, y \ z(x, y) = c\}$. Here the “semantic segmentation” $Z[X, Y]$ is analogous to the phoneme sequence $z[T]$ in CTC. Unlike the CTC model, the label S is a set rather than a sequence.

We assume a CNN (with convolutions of stride 1 to preserve spatial dimensions) followed by a softmax at each pixel to get a probability $P_{\Phi}(z[x, y] = c)$ for each pixel location (x, y) and each $c \in \mathcal{C} \cup \{\perp\}$ and where each pixel location has an independent probability distribution over classes. To simplify notation we can reshape the pixel locations into a linear sequence and replace $z[X, Y]$ by $z[T]$ with $T = X \times Y$.

Define

$$S_t = \{c \in \mathcal{C} \mid \exists t \leq T \ z[t] = c\}$$

For $U \subseteq S$ define

$$F[U, t] = P(S_t = U)$$

Note that for $|S| \leq 5$ there are at most 32 possible values of U . Give dynamic programming equations defining $F[U, 0]$ and defining $F[U, t + 1]$ in term of $F[U, t]$.
